

dotnet new mvc -n <project name>

- Creates a new ASP.NET Core MVC (Model-View-Controller) web application project with the specified name.

Example:

```
dotnet new mvc -n MyWebApp
```

This creates a new folder called "MyWebApp" containing a basic MVC project structure with controllers, views, and models folders already set up.

dotnet build

- Compiles the project and its dependencies, checking for errors without running the application.

Example:

```
dotnet build
```

Run this from within your project directory. It compiles the code and reports any compilation errors or warnings.

dotnet run

- Compiles and executes the application in one step.

Example:

```
dotnet run
```

Run this from your project directory to start your application. For a web app, it will typically start a local web server.

dotnet watch run

- Runs the application and automatically restarts it whenever you save changes to your code files.

Example:

```
dotnet watch run
```

Useful during development - make changes to your code, save the file, and the app restarts automatically without manually stopping and restarting.
